

Abstract

This thesis is focused on summarising basic knowledge about the diagnosis cerebral palsy (CP), describing the development of an individual with CP and on compiling a care plan from birth up to adulthood. In the theoretical part knowledge about historical aspects, risk factors, prevalence, diagnostics, classification and comorbidities of CP is summarized. In the theoretical part are also included the characteristics of each life period of an individual with CP and interventions that are usually indicated during the time, including a comparison with foreign approaches. The practical part is an overview of intervention indications in relation to age compiled from data of patients' medical documentation. These data were processed into a timeline, which is a part of this thesis.
